Robinhood Chain
Market Intelligence Report

A holistic read of the tokenized-equity corpus: trends, flow, and the largest traders

SNAPSHOT

Captured	**2026-07-04 00:00 UTC (Robinhood Chain, id 4663)**
Corpus	**50 tokenized assets · 3,586 notable transfers · 112 wallets**
Total on-chain $ flow	**$931,820 (see caveat: 97% is non-organic)**
Provenance	**On-chain fangorn commit · every record CID-addressed**

Generated via the market-mesh MCP (quickbeam Financial Knowledge Mesh). price mirrors the real equity (Blockscout exchange_rate) and is trustworthy; marketCap / holders / totalSupply / volume describe only the on-chain tokenized wrapper, not company fundamentals.

Executive summary

The Robinhood Chain corpus is a live, on-chain-verifiable market of 50 tokenized US equities and ETFs. Screened holistically, the data tells two very different stories depending on whether you read the headline volume or the wallet-level flow underneath it.

97%

of all dollar volume is a single BABA wash cycle, not demand

324

holders on TSLA — the most-distributed token; genuine adoption

3 bots

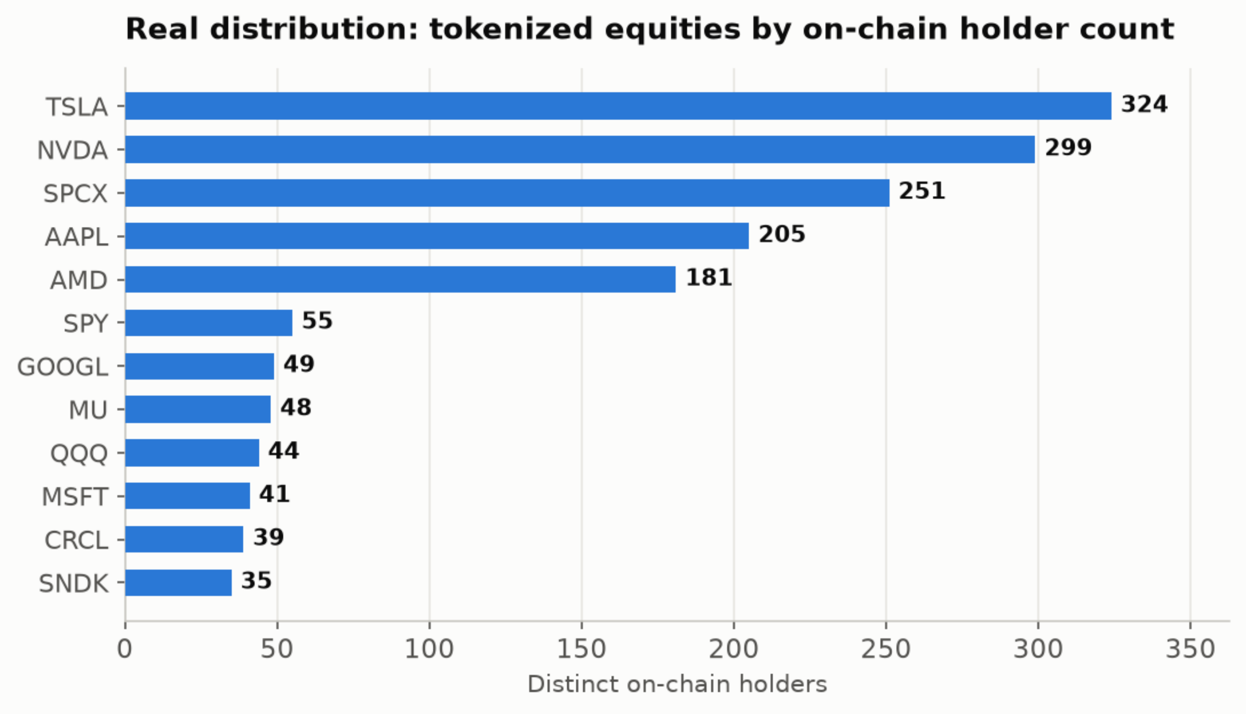
drive 5,579 of 7,172 transfer legs by cycling near-zero dust

Key findings:

1. Genuine adoption concentrates in a handful of mega-caps. TSLA (324), NVDA (299), SPCX (251), AAPL (205) and AMD (181) hold real, distributed on-chain holder bases. Most of the other 45 assets have single-digit holders.
2. Headline volume is almost entirely fabricated. $905,735 of the $931,820 total dollar flow is one Alibaba (BABA) operation: a 0x0 mint feeds the same token parcels through a fixed 5-wallet chain. BABA shows the largest recentVolume in the corpus (9,418) on just 8 holders.
3. Transfer COUNT is dominated by dust bots. Three wallets (0xC94135b6, 0x2F4579Ca, 0x624C6Dbb) generate ~5,600 transfer legs cycling ~0-value amounts across ~24 large-cap tokens — inflating recentTransfers (capped at 100 for every mega-cap) without moving value.
4. The reliable signals are price (equity-mirrored) and holders (distribution). recentVolume and recentTransfers should be treated as adversarial until the flow passes an authenticity check.

1 · Real distribution — who actually holds

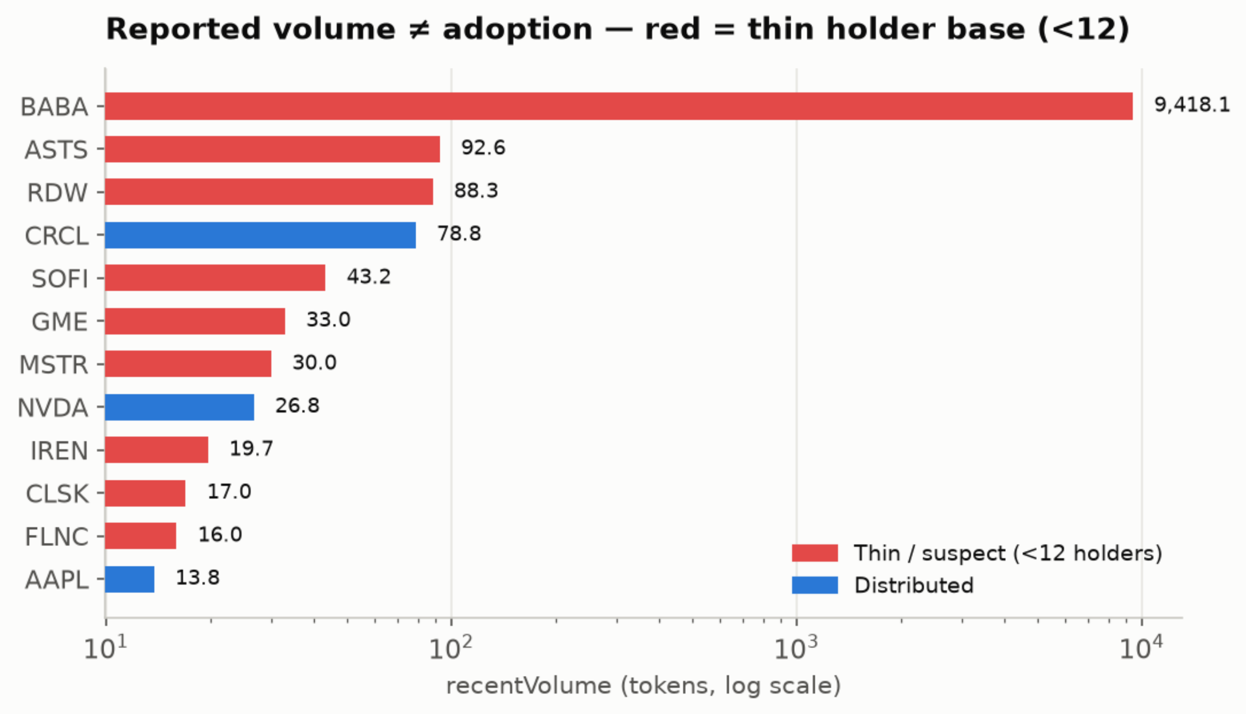
Holder count is the cleanest adoption signal in the dataset: it can't be inflated by self-transfers the way volume and transfer-count can. Distribution is steeply concentrated — five tokens carry 180+ holders each while the long tail sits in the single digits.



Read: the tokenized wrapper has meaningful organic distribution only at the very top of the mega-cap set. A token with a large market cap but <10 holders (e.g. most ETFs and the smaller names) is thinly wrapped — its on-chain figures reflect a few large parcels, not a market.

2 · Volume is not adoption

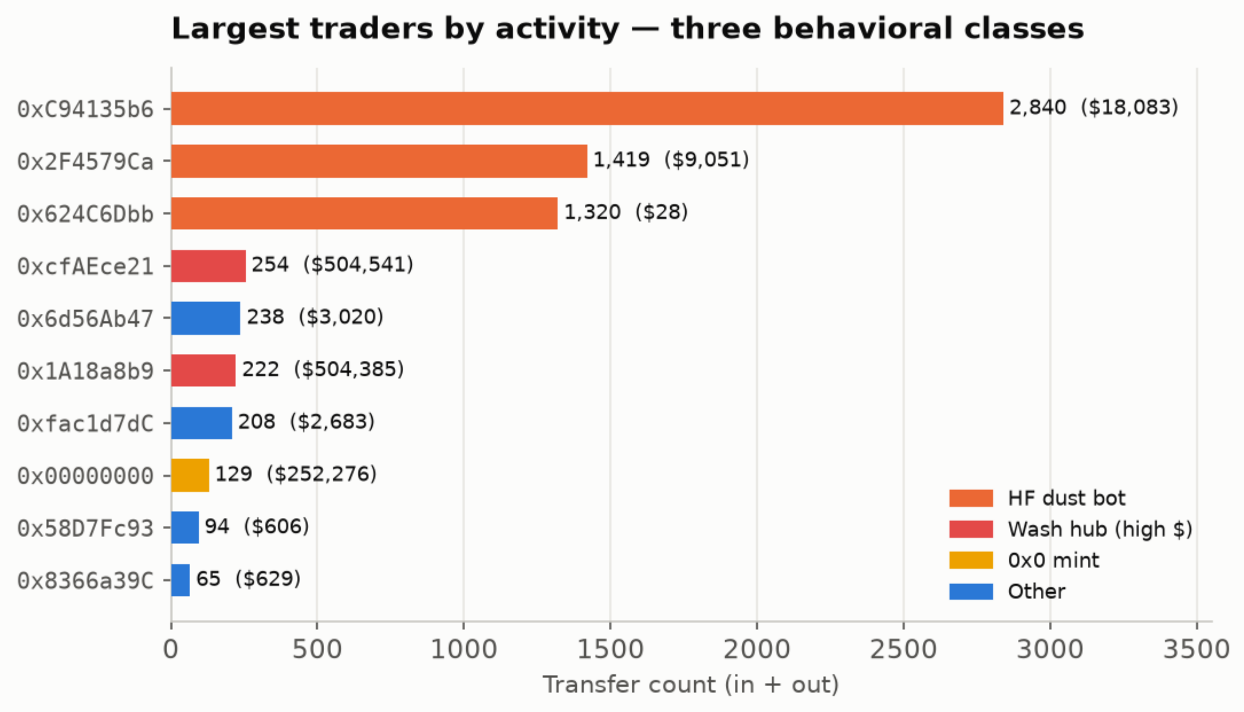
Ranking the same assets by recentVolume produces an almost inverted list. BABA tops it with 9,418 on only 8 holders; the genuinely-distributed mega-caps (AAPL, TSLA, MSFT) report near-zero volume. High volume on a thin holder base is the classic wash-trading fingerprint.



Every red bar is a token whose reported activity is not backed by a distributed holder base. The next section traces where that 'volume' actually comes from.

3 · The largest traders

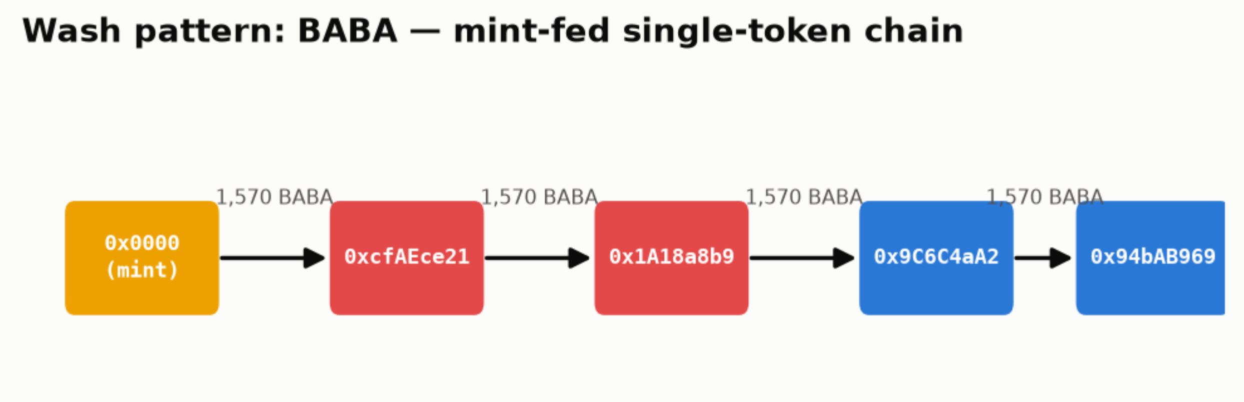
Across 112 wallets, activity splits into three sharply different behavioral classes. The most active wallets by count move almost no money; the wallets moving the most money act only a few times.



Class	Signature	What it is
HF dust bots	2,840 / 1,419 / 1,320 tx	Cycle ~0-value dust across ~24 mega-caps; inflate transfer count
Wash hubs	$504k each, ~250 tx	0xcfAEce21 <-> 0x1A18a8b9 relay the minted BABA parcels
0x0 mint	$252k, 129 tx	Origin of the wash supply — feeds the hubs
One-shot endpoints	1-2 tx, $150-300k	0x9C6C4aA2 / 0x94bAB969 terminate the BABA chain

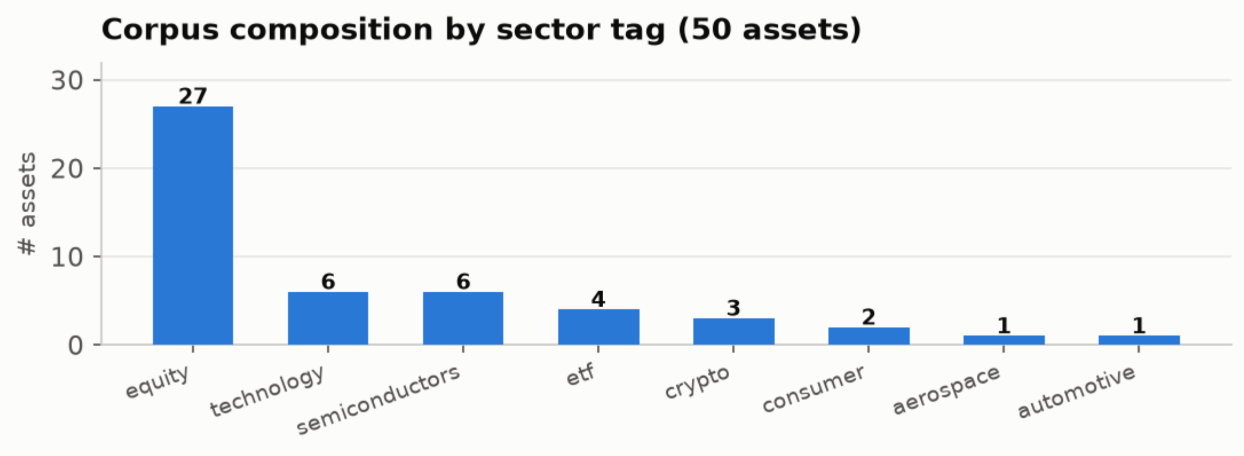
4 · Anatomy of the wash trade

BABA is the entire dollar-volume story. A 0x0000 mint issues a parcel that then hops through a fixed chain of wallets in the same block — the identical token amount reappearing at each hop is the tell. The pattern repeats at 1,570 / 561 / 350 / 126-token sizes, manufacturing ~$906k of 'volume' that is one actor moving the same coins in a circle.



Same 1,570 tokens ($150,987) hop through 5 wallets in one block — repeated at 561, 350, 126 token sizes.

5 · Corpus composition & methodology



Sector tags are coarse (many names fall under a generic 'equity' label) but the corpus skews toward technology, semiconductors and crypto-proxy names (COIN, MSTR, CRCL) — consistent with the retail-momentum universe Robinhood Chain wraps.

How this was produced

Data was pulled live through the market-mesh / quickbeam MCP: refresh -> semantic screen of all 50 Assets -> full 3,586-Transfer flow extract -> wallet-level aggregation and authenticity checks (repeated identical values, mint-fed chains, circular A->B->C wallet sets). Flow-authenticity flags follow the market-mesh wash-detection recipe.

Caveats

- On-chain metrics (marketCap, holders, totalSupply, volume) describe the tokenized wrapper, NOT the underlying company. price is the only equity-accurate field.
- recentTransfers is capped at 100, so mega-cap transfer counts are floored, not measured.
- Findings are point-in-time as of the snapshot CID above; the pipeline re-publishes every ~1-3 min.
- Every figure here traces to the on-chain commit bafkreiffppi...szae, published by 0x147c24c5...45ef6.
